Implementation plan for Ai integration in Crescent

Given the domain's current compromised state (hosting an illegitimate "Komeri" clone), this plan rejects the existing codebase entirely. Instead, it proposes a reconstruction of the legitimate **Crescent Technosofts** business identity, focusing on its historical strength: **Enterprise Hospital Management Systems (HMS)**.

The proposed system is **"Crescent HMS 2.0: AI-Integrated Healthcare Platform."**

1 Practical Implementation Strategy

1.1 Real-World Use Case Alignment

- **Problem:** Traditional Hospital Management Systems are data silos. They record data but don't *act* on it. Administrative bottlenecks (scheduling), clinical burnout (documentation), and patient leakage (poor engagement) are critical failures.
- **Solution:** A unified SaaS-based HMS that uses AI to automate patient intake, predict resource demand, and streamline clinical documentation.

1.2 Functional Architecture Breakdown

- **Frontend (The Experience Layer):**
  - **Portals:** Patient App (Mobile), Doctor Dashboard (Web/Tablet), Admin Console (Web).
  - **Tech: React Native** (Mobile) + **Next.js** (Web).
- **Backend (The Logic Layer):**
  - **Core Services:** Patient Records, Billing, Inventory (CRUD operations).
  - **AI Orchestrator:** Dedicated service to handle model inference and context management.
  - **Tech: NestJS (Node.js)** for core business logic; **FastAPI (Python)** for AI/ML microservices.
- **Database (The Truth Layer):**
  - **Relational: PostgreSQL** (Patient data, financial transactions).
  - **Vector Store: Pinecone** or **pgvector** (For retrieving medical protocols and patient history context for AI).
  - **Time-Series: TimescaleDB** (IoT vitals monitoring, if applicable).

1.3 Infrastructure & Deployment

- **Environment: AWS** (HIPAA-compliant configuration).
- **Containerization: Docker** images managed via **Amazon EKS** (Kubernetes) for scalability.
- **DevOps:** GitHub Actions for CI/CD.
  - *Dev:* Feature branches, mock data.
  - *Staging:* Anonymized production data replica.
  - *Production:* Multi-AZ deployment with auto-scaling.

2 Complete AI Integration Plan

Selected AI Feature: "Smart Triage & Clinical Documentation Assistant"

2.1 Feature Definition

1. **Pre-Visit Triage:** An AI chatbot interacts with patients to gather symptoms, history, and urgency, summarizing this for the doctor before the visit.
2. **Automated Coding:** The AI analyzes the doctor's notes to suggest ICD-10 codes for billing.

2.2 AI Model Selection Strategy

- **Primary Engine (NLP/Reasoning): Large Language Model (LLM)**.
  - *Recommendation:* **Azure OpenAI Service (GPT-4 Turbo)**.
  - *Reasoning:* High reasoning capability, HIPAA compliance (BAA available), and strictly defined data privacy boundaries compared to public APIs.
- **Fallback/Cost-Optimization: Fine-tuned Llama 3 (70B)** hosted on AWS SageMaker.
  - *Use Case:* High-volume, non-critical summarization tasks to save API costs.

2.3 Data Pipeline & Pre-processing

1. **Ingestion:** Voice-to-Text (using **OpenAI Whisper**) or Direct Text Input.
2. **Sanitization:** PII Redaction (using **Microsoft Presidio**) *before* data hits the LLM to ensure privacy compliance.
3. **Context Injection (RAG):** Retrieve patient's past medical history + hospital triage protocols from the Vector Database (pgvector).
4. **Prompt Engineering:** Structured system prompts ensuring the AI acts as a "Medical Assistant" and strictly avoids diagnosis (outputting only summaries and risk flags).

2.4 Backend Integration Architecture

- **Communication:**
  - Frontend sends chat data via **WebSockets** (for real-time typing feel) to the **API Gateway**.
  - API Gateway routes to the **AI Service (FastAPI)**.
- **Asynchronous Processing:**
  - Heavy tasks (e.g., generating a full visit summary) are pushed to a **Redis Queue (BullMQ)**.
  - A worker service processes the queue and pushes the result back to the client via WebSocket/Server-Sent Events (SSE).

2.5 Performance & Failover

- **Caching:** Semantic Caching (Redis) to store common symptom queries and responses (e.g., "Flu symptoms advice") to avoid hitting the LLM API repeatedly.
- **Circuit Breaker:** If Azure OpenAI latency > 3s, fallback to a simpler rule-based triage logic or a smaller, faster local model.

3 System Architecture Design

3.1 Architecture Data Flow

1. **User Input:** Patient describes symptoms in the Mobile App.
2. **Gateway & Security:** Request hits **AWS API Gateway** → Validated by **Auth0** (JWT).
3. **Orchestration (FastAPI):**
   - Service fetches Patient History from **PostgreSQL**.
   - Service fetches Triage Protocols from **Vector DB**.
   - Service sanitizes data (removes Name/SSN).
4. **AI Inference:** Combined Context + User Query sent to **GPT-4**.
5. **Response Handling:**
   - AI returns a structured JSON: `{ "urgency": "High", "summary": "...", "recommended_specialty": "Cardiology" }`.
6. **Action:** Backend books a provisional slot and notifies the triage nurse.

3.2 Security Considerations

- **Zero-Trust Network:** AI services sit in a private subnet; no public internet access except via NAT Gateway to Azure/OpenAI.
- **Data Residency:** All patient data remains in the primary region (e.g., AWS us-east-1); no training on customer data allowed by the API provider.

3.3 Cost Optimization

- **Token Management:** Summarize conversation history aggressively to reduce prompt token counts.
- **Tiered Intelligence:** Use a cheaper model (GPT-3.5 or local Llama) for greeting/routing and only call GPT-4 for clinical summarization.

4 Implementation Roadmap

Phase 1: Foundation (Weeks 1-4)

- **Goal:** Reclaim domain, set up AWS environment, deploy "Hello World" HMS core.
- **Action:** Secure `crescenttechnosofts.com`. Setup Next.js frontend + NestJS backend.
- **Deliverable:** Employee Login & Basic Patient CRUD.

Phase 2: The Data Layer (Weeks 5-8)

- **Goal:** Structure the medical data for AI.
- **Action:** Implement PostgreSQL schema. Set up pgvector. Build the "Ingestion Pipeline" to digitize fake/test medical records.
- **Deliverable:** Searchable patient database.

Phase 3: AI Pilot - "Smart Triage" (Weeks 9-14)

- **Goal:** First AI integration.
- **Action:** Build FastAPI microservice. Connect to Azure OpenAI. Implement PII redaction middleware.

- **Testing: Red Teaming** the AI (trying to force it to give wrong medical advice/hallucinate).
- **Deliverable:** Beta Patient App with "Symptom Checker".

Phase 4: Production & Compliance (Weeks 15-20)

- **Goal:** Go Live.
- **Action:** HIPAA audit. Penetration testing. Load testing (simulating 1000 concurrent patients).
- **Deliverable:** Full launch of **Crescent HMS 2.0**.
